ABSTRACT

Comparative genomics of H5N1 virus will help to analyze the evolution of subtypes of Influenza A viruses and to know the differences in their genes and surface proteins which could be useful in understanding their mode of action. In this study we have compared all gene segments and proteins of H5N1 with other types of influenza-A viruses such as H1N1, H2N2, H3N2 and H9N2. The comparative analysis revealed that H5N1 was phylogenetically closer to H9N2. Homology percentages of eight genes of H1N1, H2N2, H3N1, H5N1 and H9N2 were calculated. Average homology of genes of aligned segments in subtypes of H5N1, H9N1 was found to be 81.5%.

INTRODUCTION

An influenza pandemic is a global outbreak of disease that occurs when a new influenza A virus appears or “emerges” in the human population, causes serious illness, and then spreads easily from person to person worldwide [1]. Past influenza pandemics have led to high levels of illness, death, social disruption, and economic loss [2]. Influenza viruses come under the class of orthomyxo-viridae family, having a single stranded negative sense, segmented RNA genome in an enveloped virian [3]. There are three types of Influenza viruses: A, B and C, differentiated by antigenic differences in their nucleoprotein and matrix protein. The genome of influenza consists 8 RNA segments and encodes 10 proteins including the internal structural proteins, nucleocapsid protein (NP), and the two matrix proteins (M1 & M2). The segmented nature of the genome also allows for the exchange of entire genes between different viral strains when they cohabitate the same cell [4].

The surface proteins hemagglutinin (HA) and neuraminidase (NA) extensively studied that are essential to the virus life cycle and the antigenic variations in the surface glycoproteins are used to subtype influenza A [5]. In addition, three of the influenza polypeptides are associated with RNA polymerase activity (PA, PB1, and PB2). The RNA binding non-structural protein (NS) contributes to viral pathogenicity and plays a central role in the prevention of interferon mediated antiviral response [6].

The H5N1 virus, an avian influenza virus (Bird flu) can cause illness in many species including humans by undergoing the process of Antigenic shift in some intermediate host, generally a pig or chicken [7]. H5N1 can be considered as a pandemic threat as it can move from areas where it is endemic to other parts of the world through migrating water fowl [8]. H5N1virus has mutated through antigenic drift into dozens of highly pathogenic varieties, but all currently belonging to genotype Z of avian influenza virus H5N1 [9-10].

This infection of humans coincided with an epizootic (an epidemic in nonhumans) of H5N1 influenza in Hong Kong’s poultry population and was capable of emerging in to a panzootic disease [11]. Populations tend to have more resistance to influenza B and C, because they only undergo antigenic drift and have more similarity with previous strains [12]. Sixteen H subtypes and nine N subtypes have been identified for influenza A virus. Only one H subtype and one N subtype have been identified for influenza B virus. The most common antigenic variants of influenza A virus are H1N1 and H3N2 [13].

This study consists of comparing all the gene segments and some important proteins of H5N1 virus with other types of Influenza A viruses like H1N1, H2N2, H3N2 and H9N2. Comparative genomics of H5N1 virus will help to analyze the evolution of these subtypes and to understand the differences in their genes and surface proteins which could be useful to comprehend their mode of action and genetic drifts among these viruses.
METHODS

Data Mining

All the gene sequences and amino acid sequences of all proteins of H5N1, H1N1, H2N2, H3N2 and H9N2 should be collected from the NCBI Public Database, which is maintaining a separate public genome and proteome database for all the Influenza viruses' i.e. A, B and C types of Influenza viruses. All the subtypes studied in our project work belong to Influenza A virus. All the genes should be sorted according to their corresponding virus subtypes[14].

Comparative study of genes and amino acid sequences

The analyzed genes and proteins should be compared to have a basic idea of their evolution and know the differences in their genes and proteins and how these differences are responsible for the change in their virulence or pathogenicity. By that we can know in which aspects H5N1 is different from other subtypes and which aspects it is similar. This comparative study was done using various tools available in JEMBOSS like PLOTCON, Pretty plot, Clustal W, BLAST P, BLAST N[15-17].

Phylogenetic analysis:

The phylogenetic analysis of the various subtypes of Influenza A virus will give the idea of ancestral relationships among the subtypes. The phylogenetic analysis of the 5 subtypes selected in our study sophisticated tool like NJplot (Neighbor Joining plot) used for a better understanding. Using this tool phylogenetic tree can be constructed for all the eight gene segments of the selected 5 subtypes.

RESULTS AND DISCUSSION

Multiple alignments of gene segments of Influenza-A subtypes

The eight genes of H1N1, H2N2, H3N1, H5N1 and H9N2 have been aligned by using the multiple alignment tool Clustal W and their percentage of homology is presented in Table (1). Based on homology percentages it was observed that H5N1 showed highest similarity with H9N2. The similarity regions of nucleotides in segment 2 of H1N1, H2N2, H3N2, H5N1 and H9N2 were analyzed by Pretty plot and was found that segment-2 of H5N1 similar to H9N2 (figure 1). The aligned regions of these gene segments were merged using Plotcon for identification of conserved regions. Earlier it was reported as 87 conserved regions were identified in the influenza genome and in avian host strains, the segments NS, M show the most conservation (94.5%), followed by the PB1, NP, PA, and finally the PB2 segment. In the swine strains the M segment shows the most conservation followed by the segments NP, PB2, PA, and finally PB1[18].

The nucleotide sequences of all segments of influenza-A virus subtypes similar regions were aligned by Clustal W. Based on the aligned regions of virus subtypes, it was found that segment-6 of H5N1 showed maximum similarity with H1N1, where as other segments (2, 3, 4, 5, 7 and 8) showed similarity with H9N2 (figure 2).
g. Segment-8

Figure 2: Multiple Sequence alignments of different segments i.e. seg-2 to seg-8 (a to g) of subtypes (H2N2, H5N1, H1N1, H3N1 and H9N2) of influenza-A virus. In H5N1 all the segments shows maximum aligned regions with H9N2, except segment -6 of H5N1 and it shows more aligned regions with H1N1.

Phylogenetic Analysis of Segments of Subtypes of Influenza-A

The gene segment-2 of H5N1 shows close resemblance compared with segment -2 of H9N2. The influenza-A subtypes of H2N2 and H5N1 are closely related and the cluster of gene segments -2 of H1N1 and H9N2 is distantly related compared with H3N2 as shown in figure (3). The unrooted phylogenetic tree of segment 3 in the selected five subtypes of Influenza A virus presented in figure (4 & 5). There is no common ancestor for all the third segments and it clearly shows the close resemblance between H5N1 and H9N2. The phylogenetic tree of segment 4 in the selected five subtypes of Influenza A virus showed the close resemblance between H3N2 and H2N2 (figure 6 & 7). The gene segment 5 in the selected five subtypes of Influenza A virus shows the close likeness between H5N1 and H9N2 in figure (8 & 9). Phylogenetic tree of segment 6 in the selected five subtypes of influenza-A virus reveals close semblance between H5N1 and H1N1. The cluster of these gene segments are distantly related to H9N2 as shown in figure (11). The phylogenetic tree analysis of segment 7 and segment-8 in the selected five subtypes of Influenza A virus shown the close resemblance between H5N1 and H9N2 (figures 12,13&14). The haemaglutinin of selected subtypes of influenza-A shows close resemblance between H5N1 and H1N2 (figure 15,16&17). Similarly, neuraminidase of subtypes of influenza-A reveals close relation between H5N1 and H1N1 (figures 18, 19 & 20).
